

STAT406- Methods of Statistical Learning Lecture 9

Matias Salibian-Barrera

UBC - Sep / Dec 2017

**I CAN
WORK
WITH THE
MEANS.**

**BUT I'D
RATHER
PARTY
WITH THE
OUTLIERS.**

Kernel smoothers

- We are interested in estimating

$$f(x) = E(Y|X = x)$$

- Given a sample $(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$

$$\hat{f}(x) = \text{average}\{y_j : x_j = x\}$$

$$\hat{f}(x) = \text{average}\{y_j : x_j \text{ is close to } x\}$$

Kernel smoothers

- More formally

$$\hat{f}(x) = \text{average} \left\{ y_j : |x_j - x| \leq h \right\}$$

$$\hat{f}(x) = \frac{1}{n_x} \sum_{i: |x_i - x| \leq h} y_i$$

$$\hat{f}(x) = \frac{\sum_{i: |x_i - x| \leq h} y_i}{\sum_{i: |x_i - x| \leq h} 1}$$

Kernel smoothers

- More formally

$$\hat{f}(x) = \frac{\sum_{i=1}^n K(x_i, x, h) y_i}{\sum_{j=1}^n K(x_j, x, h)}$$

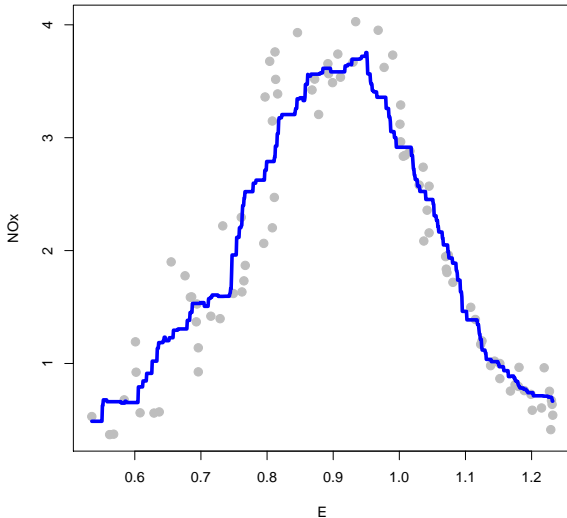

where

$$K(x_j, x, h) = W\left(\frac{x_j - x}{h}\right)$$

and

$$W(t) = \begin{cases} 1 & \text{if } |t| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

Kernel smoothers - $h = 0.07$

Kernel smoothers

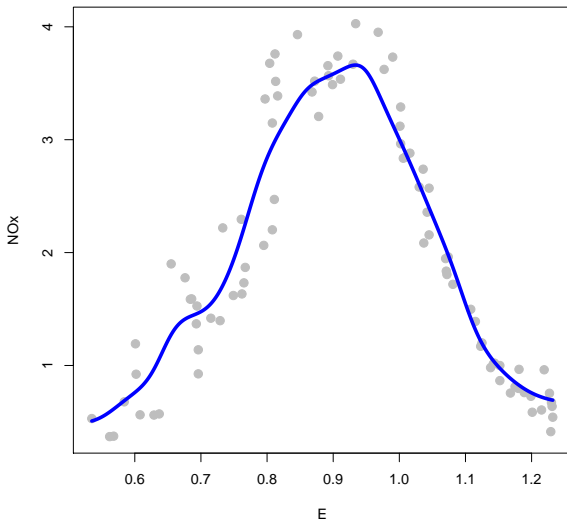

- Discontinuities come from $W(t)$
- Use a smooth kernel

$$K(x_j, x, h) = W\left(\frac{x_j - x}{h}\right)$$

with

$$W(t) = \begin{cases} 1 - t^2 & \text{if } |t| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

Kernel smoothers - $h = 0.03$

Kernel smoothers

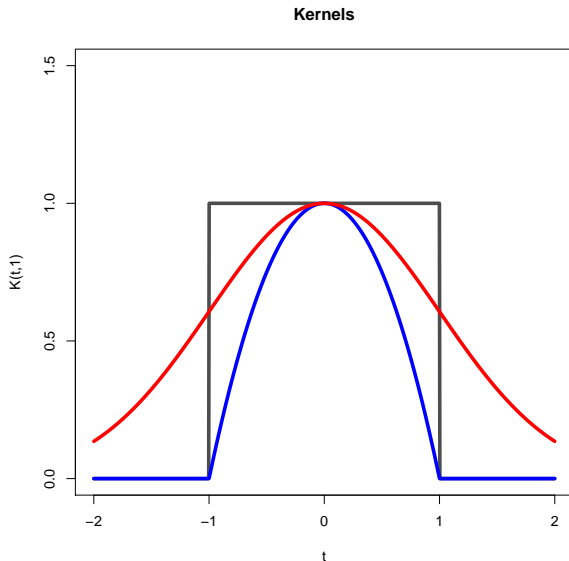

- Other kernels...

$$K(x_j, x, h) = W\left(\frac{x_j - x}{h}\right)$$

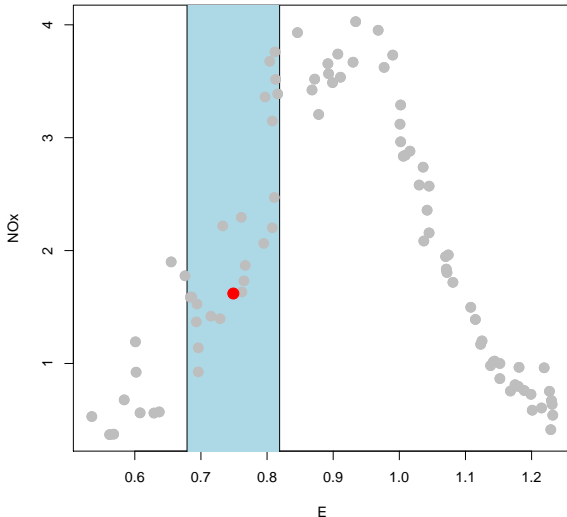

with

$$W(t) = \phi(t) \propto \exp\left(-t^2/2\right)$$

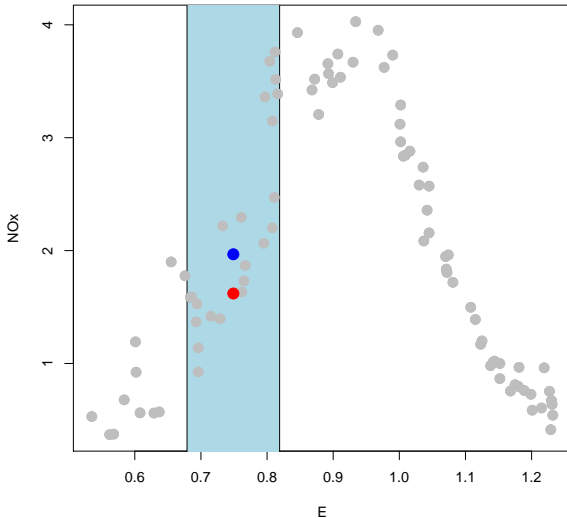

Kernel smoother in action

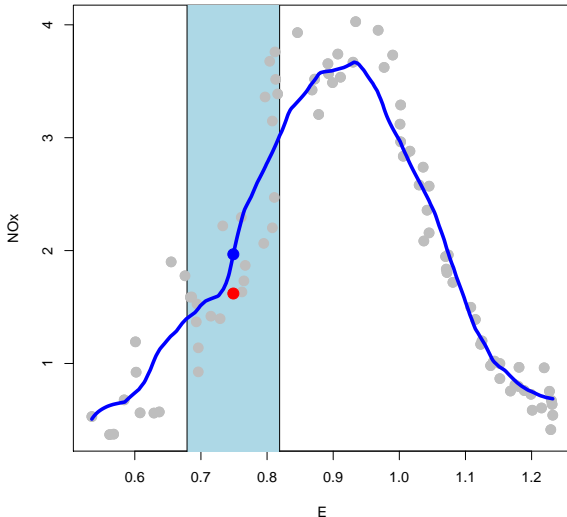

Kernel smoother in action

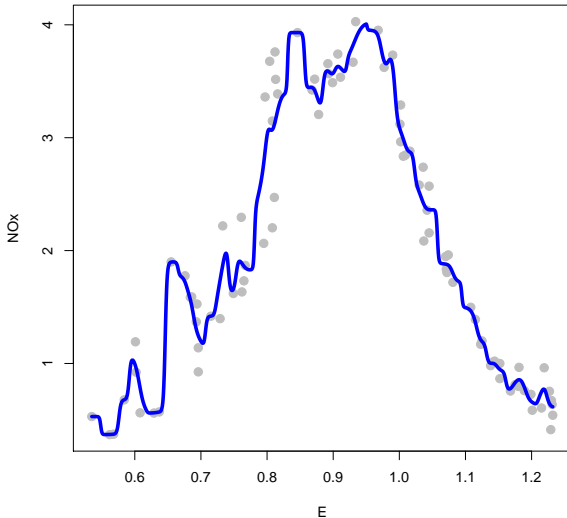

Kernel smoother in action

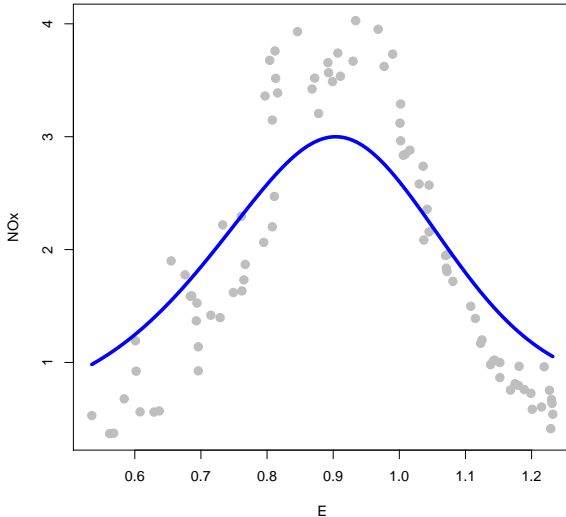

Kernel smoother in action

Small bandwidth

Larger bandwidth

Kernel smoothers

- Note that the locally weighted average

$$\hat{f}(x) = \frac{\sum_{i=1}^n K(x_i, x, h) y_i}{\sum_{j=1}^n K(x_j, x, h)}$$

solves

$$\hat{f}(x) = \arg \min_{\mu} \sum_{i=1}^n K(x_i, x, h) (y_i - \mu)^2$$

- “Local constant” fit

Kernel smoothers

- A Taylor expansion suggests

$$f(x) = f(x_0) + f'(x_0)(x - x_0) + R$$

for small $|x - x_0|$

$$f(x) \approx f(x_0) + f'(x_0)(x - x_0) = \\ \beta_0(x_0) + \beta_1(x_0)x$$

a “local” line

- “Local linear regression”

Kernel smoothers

- At each point \mathbf{x} we find

$$\hat{\beta}(\mathbf{x}) = \arg \min_{\beta_0, \beta_1} \sum_{i=1}^n K_h(\mathbf{x}_i, \mathbf{x}) (y_i - \beta_0 - \beta_1 \mathbf{x}_i)^2$$

which is just weighted least squares

- There is a closed form expression for $\hat{\beta}(\mathbf{x})$

Kernel smoothers

- We have that $\hat{\beta}(\mathbf{x})$ is

$$\hat{\beta}(\mathbf{x}) = (\mathbf{X}' \mathbf{W}_{\mathbf{x}} \mathbf{X})^{-1} \mathbf{X}' \mathbf{W}_{\mathbf{x}} \mathbf{Y}$$

$$\mathbf{X} = \begin{pmatrix} 1 & x_1 \\ 1 & x_2 \\ \vdots & \vdots \\ 1 & x_n \end{pmatrix}$$

$$\mathbf{W}_{\mathbf{x}} = \text{diag} (K_h(x_1, \mathbf{x}), \dots, K_h(x_n, \mathbf{x}))$$

Kernel smoothers

- An alternative representation, $\hat{\beta}(\mathbf{x})$ solves

$$\arg \min_{\beta_0, \beta_1} \sum_{i=1}^n K_h(\mathbf{x}_i, \mathbf{x}) (y_i - \beta_0 - \beta_1 (\mathbf{x}_i - \mathbf{x}))^2$$

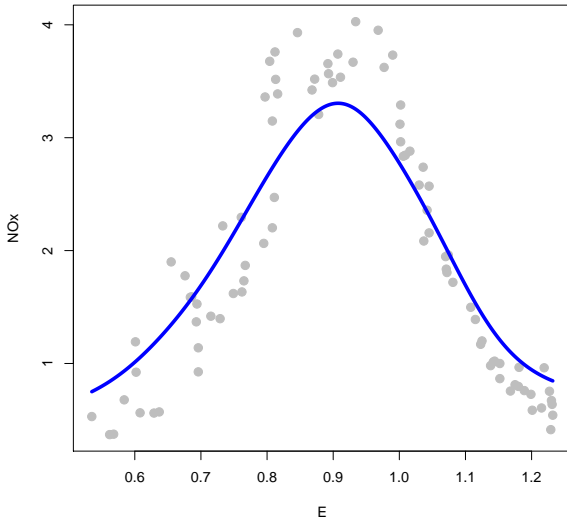

then the fit at \mathbf{x} is $\hat{f}(\mathbf{x}) = \hat{\beta}_0(\mathbf{x})$

- Note that

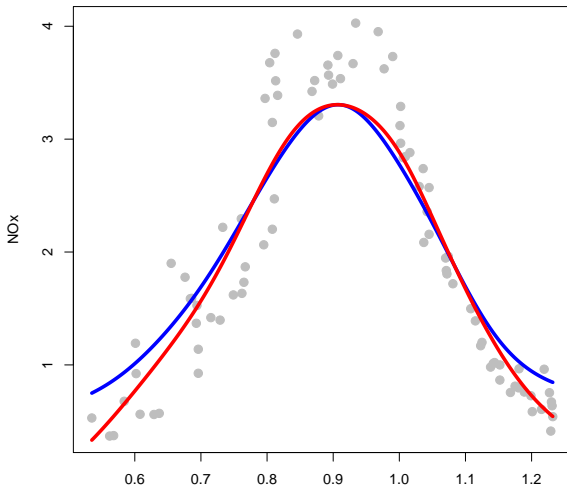

$$\hat{f}(\mathbf{x}) = \mathbf{e}'_1 \left(\tilde{\mathbf{X}}' \mathbf{W}_x \tilde{\mathbf{X}} \right)^{-1} \tilde{\mathbf{X}}' \mathbf{W}_x \mathbf{Y}$$

- Local linear fits work better at the boundaries

Local mean - $h = 0.07$

Local mean & local linear - $h = 0.07$

Kernel smoothers

- These fits are linear
- In other words:

$$\hat{f}(\mathbf{x}) = \ell(\mathbf{x})' \mathbf{Y}$$

hence, if Y_i are independent with $\text{Var}(Y_i) = \sigma^2$, $1 \leq i \leq n$, then:

$$\text{Var}(\hat{f}(\mathbf{x})) = \|\ell(\mathbf{x})\|^2 \sigma^2$$

Kernel smoothers

- We can also consider quadratic fits

$$\hat{\beta}(x) = \arg \min_{\beta} \sum_{i=1}^n K(x_i, x, h) (y_i - \beta' \mathbf{z}_i)^2$$

where

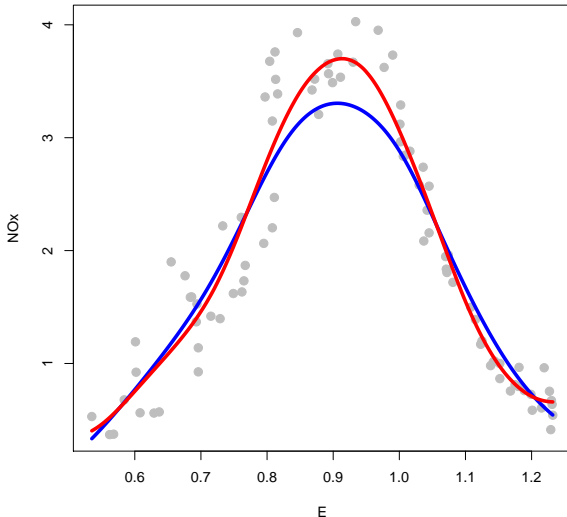

$$\mathbf{z}_i = \begin{pmatrix} 1 \\ x_i - x \\ (x_i - x)^2 \end{pmatrix}$$

and again

$$\hat{f}(x) = \hat{\beta}(x)_1 = \mathbf{e}'_1 \hat{\beta}(x) \quad (\text{the intercept})$$

- Better fit for “valleys” and “peaks”

Local lin. & quad. - $h = 0.07$

Kernel smoothers

- We can use higher degrees:

$$\hat{\beta}(x) = \arg \min_{\beta} \sum_{i=1}^n K(x_i, x, h) (y_i - \beta' \mathbf{z}_i)^2$$

where

$$\mathbf{z}_i = \begin{pmatrix} 1 \\ x_i - x \\ \vdots \\ (x_i - x)^p \end{pmatrix}$$

$$\hat{\beta}(x) = (\mathbf{Z}' \mathbf{W} \mathbf{Z})^{-1} \mathbf{Z}' \mathbf{W} \mathbf{Y}$$

$$\hat{f}(x) = \mathbf{e}_1' \hat{\beta}(x) = \ell(x)' \mathbf{Y}$$

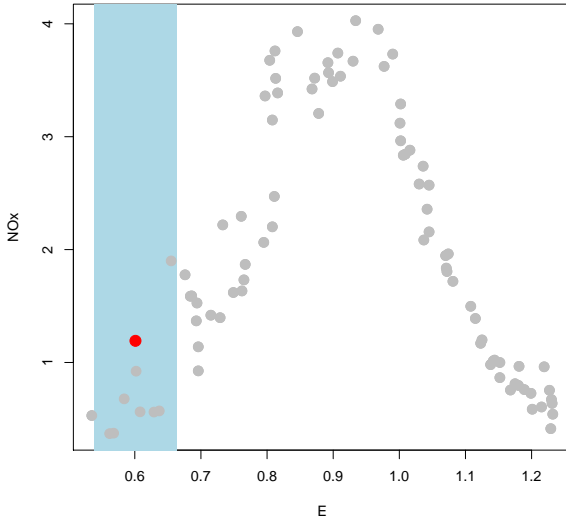

Varying bandwidths...

- Nearest neighbours?
- Use a different h for each x_0

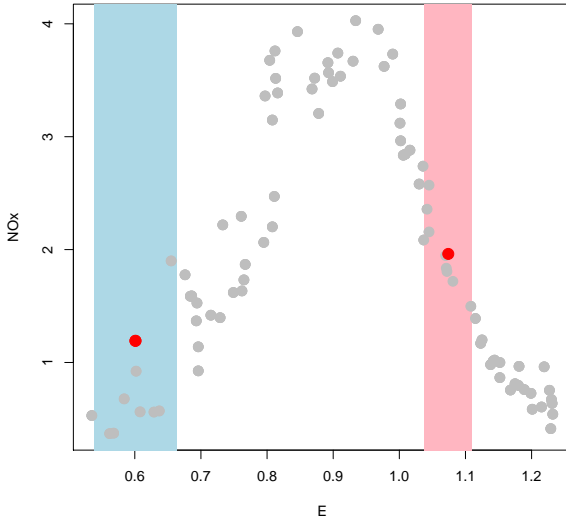

$$\min_{\beta} \sum_{i=1}^n K_{h(x_0)}(x_i, x_0) (y_i - \beta_0 - \beta_1(x_i - x_0))^2$$

- Make the window wider to avoid “empty” or “sparse” windows
- For example, we want 10% of our sample in **every window**

Varying window, $\alpha = 0.10$

Varying window, $\alpha = 0.10$

Varying bandwidths...

- More in general: let $\alpha \in (0, 1]$ and choose

$$h(\mathbf{x}_0) = d_{([n\alpha])}$$

where

$$d_j = |\mathbf{x}_j - \mathbf{x}_0| \quad j = 1, \dots, n$$

- Always have α 100 % of the points in each window
- This, again, is a linear smoother:

$$\hat{f}(\mathbf{x}_0) = \mathbf{e}'_1 \hat{\beta}(\mathbf{x}_0) = \ell(\mathbf{x}_0)' \mathbf{Y}$$

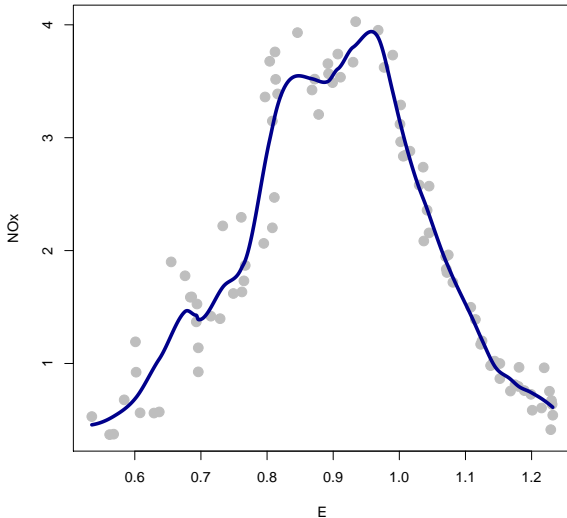

Varying bandwidths...

- This is what `loess` does in R
- Pay attention to the argument `family`
- What kernel does it use?
- Can you reproduce what `predict` does?

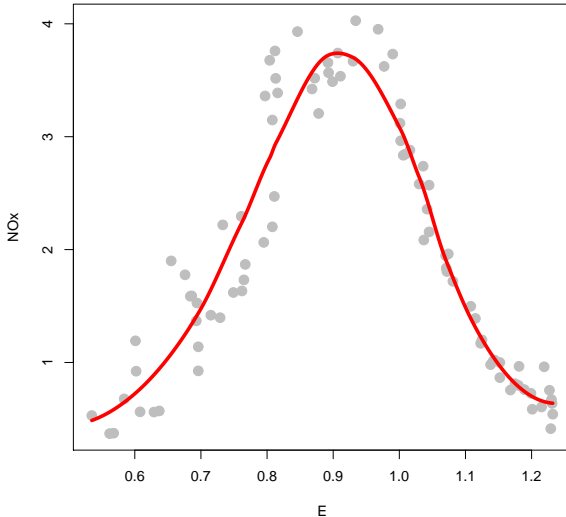

Varying bandwidths...

```
> plot(NOx ~ E, pch=19, col='gray', cex=1.5,  
      data=ethanol)  
  
> a <- loess(y~x, span=0.2, degree=2)  
  
> xt <- seq(min(x), max(x), length=1000)  
  
> yh <- predict(a, newdata=data.frame(x=xt))  
  
> lines(xt, yh, lwd=4, col='darkblue')
```

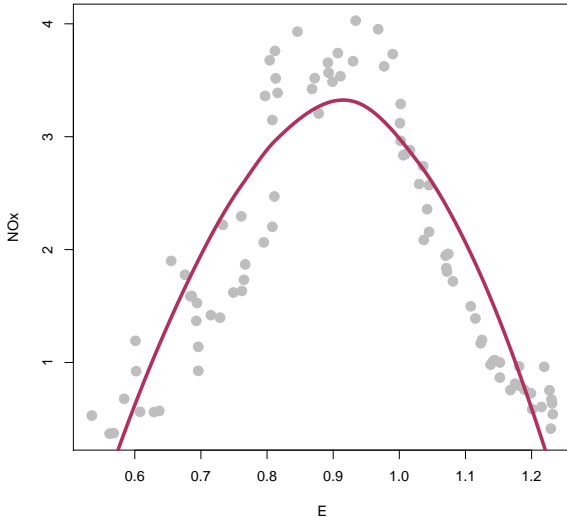

Degree=2, span = 0.2

Degree=2, span = 0.5

Degree=2, span = 1

Degree=2, **span = 2?**
